The Biodynamic Model (BM)

A means to improve sediment bioaccumulation protocols and a potentially regulatory tool

Henriette Selck¹, Samuel N Luoma², Marie-Noële Croteau³

Contaminant accumulation from sediment is important

Denosit-feeders

- Live by extracting organic matter from sediment
- Particle ingestion: main route of contaminant uptake*
- Bioturbate: mix and irrigate sediment

=> Important role in remobilization of sedimentassociated contaminants to higher trophic levels

*E.g., Selck et al. 1998; 2003a,b

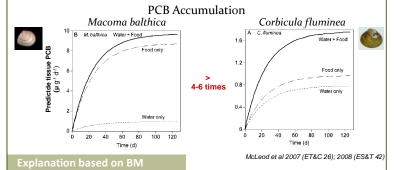

Widely used bioaccumulation (B) models, e.g., FIAM (Free Ion Activity Model) and BLM (Biological-Ligand Model) predict B based on dissolved metal concentration

Challenges

- · Other potential uptake routes exists
- Excluding dietary uptake will for some contaminants severely underestimate accumulation and thus internal exposure.

Example 1: Organics (PCB)

BM model used to explain why the body burden of *M balthica* was 4-6 times higher than for *C fluminea* despite that total sediment PCB was similar between field sites

Based on BM, McLeod et al. (2008) demonstrated that the lower uptake in *Corbicula* compared to *Macoma* was related to feeding mode: for *Corbicula* (predominantly filter-feeding) the aqueous uptake is almost equally important to dietary uptake; whereas for *Macoma* (facultative deposit-feder) 90% of the body burden came from sediment ingestion.

Compared to OECD 315

BM as a means to improve sediment bioaccumulation protocols

- Experimentally require similar effort (labor, money) to conduct
- Employed for all systems, organisms and chemicals
- Not restricted to one uptake route
- Examining unidirectional uptake and efflux rates from water and diet, will
 provide information on a number of parameters (influx/efflux, AE, IR, FR etc)
- Experimental data are directly implementable in the BM model

BM allows capturing biologically driven processes governing B among species both for metals and organic compounds

Aim

To discuss the biodynamic model as a means to measure and predict bioaccumulation from various exposure routes

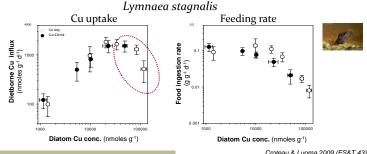

Biodynamic (kinetic) Model (BM) Experimentally derived unidirectional rate constants Water Food $C_{ss} = \frac{(ku \times Cw) + (AE \times IR \times Cf)}{(kx + k)}$ Unifying tool Functional Food conc. Food Habitat Reproductive strategy Life haboy Food conc. Water Sod conc. Water Sod conc. Unifying tool Functional Food conc. Food Conc. Food Habitat Food conc. Water Sod conc. Water Sod conc. Water Concept Sod c

Takes into account all uptake routes and allows capturing the biologically driven processes that govern bioaccumulation among species both for metals and organic compounds

 $C_{ss} : steady \ state; \ k_u : \ uptake \ rate \ constant \ (\mu g/g_{dissue}/d); \ k_e : \ loss \ rate \ constant \ (d^3); \ C_w : \ conc \ in \ water \ (\mu g/L); \ IR: \ ingestion \ rate \ (g_{food}/g_{dissue}/d); \ AE: \ assimilation \ efficiency \ (\%); \ C_f: \ conc \ in \ food \ (\mu g/g_{food}); \ k_g: \ growth \ rate \ constant \ (d^3); \ C_w : \ conc \ in \ food \ (\mu g/g_{food}); \ k_g: \ growth \ rate \ constant \ (d^3); \ C_w : \ conc \ in \ food \ (\mu g/g_{food}); \ k_g: \ growth \ rate \ constant \ (d^3); \ C_w : \ conc \ in \ food \ (\mu g/g_{food}); \ k_g: \ growth \ rate \ constant \ (d^3); \ C_w : \ conc \ in \ food \ (\mu g/g_{food}); \ k_g: \ growth \ rate \ constant \ (d^3); \ C_w : \ conc \ in \ food \ (\mu g/g_{food}); \ k_g: \ growth \ rate \ constant \ (d^3); \ C_w : \ conc \ in \ food \ (\mu g/g_{food}); \ k_g: \ growth \ rate \ constant \ (d^3); \ C_w : \ conc \ in \ food \ (\mu g/g_{food}); \ k_g: \ growth \ rate \ constant \ (d^3); \ C_w : \ conc \ in \ food \ (\mu g/g_{food}); \ k_g: \ growth \ rate \ constant \ (d^3); \ C_w : \ conc \ in \ food \ (\mu g/g_{food}); \ k_g: \ growth \ rate \ constant \ (d^3); \ C_w : \ conc \ in \ food \ (\mu g/g_{food}); \ k_g: \ growth \ rate \ constant \ (d^3); \ C_w : \ conc \ in \ food \ (\mu g/g_{food}); \ k_g: \ growth \ rate \ constant \ (d^3); \ C_w : \ conc \ in \ food \ (\mu g/g_{food}); \ k_g: \ growth \ rate \ (d^3); \ C_w : \ conc \ in \ food \ (d^3); \ co$

Example 2: Metals (Cu)

BM model used to examine the link between diet-borne Cu uptake and toxicity: i.e., why uptake influx levels off at the very high concentrations.

Explanation based on BM

Using the biodynamic model (uptake from food depends on IR and AE; AE was similar for all concentrations), Croteau and Luoma (2009) were able to ascribe the decline in diet-borne Cu uptake rates in the freshwater snails *L. stagnalis* to feeding inhibition, showing that metal accumulation is not simply a function of exposure, but also of biology, i.e., animal behavior.

Potential as a regulatory tool

Applicability of BIV

- Capacity to include site-specific & species specific characteristics:
 - Relative importance of dietary and aqueous uptake routes for organisms differing regarding habitat, feeding strategy etc.
 - Distinguish between differences in uptake related to physico-chemical properties and e.g., behavioral differences
- Predict steady state and thus calculate BAF/BSAF in a quantitative manner which undoubtedly has advantages regarding the role of B metrics in evaluation of risk criteria
- Modelled B can be validated by field samples

BM will be an improvement of sediment B protocols and has potential as a regulatory tool
